

C2_07 Practical Mastery Check - Protected Review RC4

Open only after a saved genuine Module Test attempt. Use to diagnose, then close it and do a changed retry.

Task	Expected reasoning pattern
1	Cloud service -> stored identity/credentials -> on-premises data gateway -> SQL source -> refresh -> semantic/report. A cloud SaaS source may not require the on-prem gateway, but credentials/identity and freshness still matter.
2	Granting Contributor exposes broad build privileges. Prefer the narrowest item/app audience/guest route that satisfies the certified-report need, with explicit owner and expiry/review.
3	Do not promote. The failed security rule is blocking. Repair it, retest in TEST, record PASS evidence and then run the release checklist again.
4	The job executed successfully. It does not prove the upstream partition was complete/current. Compare source watermark/partition completeness and business freshness SLA before declaring the report current.
5	Analyst owns KPI/business acceptance; analytics engineer owns transformation/semantic contract; data engineer owns source ingestion/pipeline reliability. All three record dependency/definition changes and acceptance evidence.
6	On-prem SQL requires the gateway; cloud API/SharePoint do not by default. Each source can have a different expected availability/freshness, so the report freshness rule must consider all required inputs.
7	DEV builds, TEST validates function/security/impact, PROD serves consumers. Direct PROD editing bypasses repeatable validation/traceability and complicates rollback.
8	Check audience/RLS group mapping, effective identity/role and last security/deployment change. Broad data exposure is a security incident; block further release and contain access before normal operation resumes.
9	Workspace role controls broad collaboration capabilities; item/app access narrows which artifacts are consumable; RLS/data permission narrows which rows/data an authorized consumer sees.
10	A good record separates symptom from root dependency, quantifies affected users/KPIs, assigns owner, records recovery and proves downstream behavior/freshness/security after recovery; add a prevention/control action.

Changed retry rule

Close this review. Redesign the same controls for a different domain/source mix, including at least one cloud source, one on-prem source, a failed release control and a permission incident. Save the retry separately. Module Test remains non-gating.
