

C2_09 Final Gate C - Protected Review RC4

Logistics Marketplace - open only after the complete saved genuine Gate attempt.

Protection

Do not use this as a pre-solve answer sheet. Compare it only after your own evidence is saved. Then close the review and complete the assigned changed fresh retry.

Page 1 - Objective controls and first broken dependency

- Bookings = 110 shipments totaling 281,184.93 booked charge. Initial events = 200 rows: 110 Booked + 90 Delivered. Late batch adds 20 Delivered; final events = 220 with 110 Delivered.
- Initial delivery coverage is 81.82%; after the late batch it is 100%. A pre-late-batch KPI can make every carrier look worse than the complete event history.
- Every final shipment has two event rows. Joining booking charge directly to final event rows doubles booked charge to 562,369.86 (inflation 281,184.93). Even the initial-event join inflates booked charge to 495,702.60.
- Freight invoices total 258,690.15; only 55/110 are Collected, totaling 129,452.88. Booked, invoiced and collected value are distinct definitions.
- Final event IDs are unique. The safe repair is an idempotent event merge/reconciliation, not append of a previously derived delivered-output table.

Interpretation boundary

Exact controls test grain, completeness and rerun safety. They do not create a single automatic business recommendation; definitions, period, prioritization metric and uncertainty must be explicit.

Page 2 - Reasoning audit

Decision / definitions

Separate booked shipment growth, delivery performance and invoiced/collected freight. A lane/carrier can look strong on one and weak on another.

SQL / grain

Keep Booking at Shipment, Event at Event and Invoice at Invoice/Shipment grain. Aggregate events to shipment-level delivery status before joining shipment financial measures.

Model / DAX

Use carrier/lane/date dimensions with separate booking, event-derived delivery and invoice measures. Do not sum booking charge across Event rows.

Failure / rerun

First broken dependency is event completeness plus derived-output idempotency. Merge the 20 late events by event_id, recompute shipment delivery state, reconcile 110 unique delivered shipments, then replace/reconcile the published output.

Executive / operations

After complete events, delivery coverage is 100% for all shipments in this fixture; do not invent a "worst carrier" from stale delivery data. Use financial/lane evidence and operational constraints for any prioritization.

Page 3 - Critical floors, repair and changed retry

- Summing shipment value after an Event-grain join
- Publishing the 81.82% stale delivery picture after the late batch exists
- Appending derived delivery output and duplicating delivered counts
- Collapsing booked/invoiced/collected value into one KPI
- No event-id/unique-shipment reconciliation or safe rerun
- Unsupported carrier causality or ownerless recommendation

Repair rule

Repair only the weak competency with a targeted exercise. Do not reopen this review while solving the changed case.

Changed fresh retry

Gate C is the final protected course retest. Close this review and solve the changed retry. If a critical weakness remains, require a new instructor-assigned case; never recycle A/B/C solutions as proof.

Evidence to save

First attempt, review diagnosis, targeted repair artifact, changed-retry submission, reconciliation/validation evidence, one failure/recovery note, privacy/security check and own-words defense.
