

C2-01 Mini-Lab - Month-End Refresh

Attempt after AX1-AX10; workbook + practice data required

SCENARIO

You own the May monthly operations pack. The source folder contains approved April and May order files, an IGNORE_backup file with an absurd value, one unmatched P99 product in May, and a June schema-drift file for the changed-retry path. The stakeholder wants the report now.

YOUR JOB

Create a release process rather than just pressing Refresh All. Confirm expected vs actual files, exclude backup files deliberately, preserve Source.Name, validate ProductID master uniqueness, surface unmatched P99, reconcile included rows and completed Net value, refresh the Pivot/report, then decide RELEASE or BLOCK.

PASS SIGNAL

The first unsafe run is visibly blocked. Every issue has a classification, owner/recovery, and rerun evidence. You publish only after all critical controls pass. The final workbook can be inherited by another analyst without relying on your memory.

Mini-Lab - Defense and changed retry

Mastery means you can repeat the control pattern

90-SECOND DEFENSE

Explain: What made the first run unsafe? Which file was expected exclusion versus real data-quality failure? Why does an unmatched master key matter? Which independent totals proved the repaired run? What exact condition would make you block release again?

CHANGED RETRY

After protected review, close it and run a quarter-end variant: the June file uses sku instead of product_id and one expected late file has not arrived. Do not 'fix' the schema by deleting the file. Record whether the process should wait, remap under an approved source-contract change, or release with an explicitly approved limitation.

EVIDENCE

Save: final workbook, query screenshots or query names/steps, expected/actual file list, Source.Name contribution table, unmatched list, critical reconciliation, BLOCK/RELEASE log, rerun evidence, and your explain-back.
